

Important note: This is a translation of the original paper Nickel, H., Remane, R. (2002): Artenliste der Zikaden Deutschlands, mit Angabe von Nährpflanzen, Nahrungsbreite, Lebenszyklus, Areal und Gefährdung (Hemiptera, Fulgoromorpha et Cicadomorpha). – Beiträge zur Zikadenkunde 5: 27-64. It is only available as pdf (<http://www.gwdg.de/~hnickel>).

Check list of the planthoppers and leafhoppers of Germany, with notes on food plants, diet width, life cycles, geographic range and conservation status

(Hemiptera, Fulgoromorpha and Cicadomorpha)

Herbert Nickel¹ and Reinhard Remane²

Abstract: An annotated check list of the planthoppers and leafhoppers of Germany is presented, with specifications of food plants, diet width, overwintering stage, annual generation numbers, geographic range and conservation status. The list includes 620 species, comprising 145 planthoppers and 475 leafhoppers. Five taxa, which were commonly considered as separate species, are treated as morphs or varieties of other species. On the other hand, in a number of cases there is evidence that a taxon hitherto regarded as a single species may comprise at least two species. Three names are declared as new synonyms. *Acericerus rotundifrons* (Ribaut 1952) *nec* Kirschbaum, 1868 is given a new name and described as *Acericerus ribauti*. Six species probably breed only irregularly, and at least four are neozoa originating from North America, Asia or the Mediterranean region.

Key words: Auchenorrhyncha, Fulgoromorpha, Cicadomorpha, check list, Germany, host plants, phytophagous insects, diet width, life cycle, geographic range, Red Data

1. Introduction

The earliest list of the German Auchenorrhyncha species was provided by Hüeber (1904) and was mainly based on the fourth edition of Puton's (1899) catalogue of Palearctic Hemiptera, which in turn was largely compiled after Fieber (1875, 1876, 1877, 1878, 1879). However, political borders at that time were very different from those of today, and research and description of genital morphology were still little developed. A new treatment published by Oshanin (1912) provided only minor addenda, since many geographic indications were only imprecise.

Only Nast (1972) provided a catalogue, in which Palearctic Auchenorrhyncha species were listed and, for the first time, took into account the taxonomic progress of systematic investigation of inner genitalia since Edwards (1877 ff.) and subsequently, Zachvatkin (1924 ff.), Ribaut (1925 ff.), China (1933 ff., but also some earlier studies), Nast (1933 ff.), Ossian-nilsson (1934 ff.) and Wagner (1935 ff.). These results had been ignored by other authors, e.g. Jensen-Haarup (1920), Blöte (1927, 1943) and Haupt (1935). Based on Metcalf's (1932 ff.) bibliographic catalogue, Nast's (1972) list comprised all species known from the Palearctic, together with indications of occurrence at country level. Later, he published a tabular over-

² Prof. Dr. Reinhard Remane, Faculty of Biology (Zoology), Philipps-Universität Marburg-Lahnberge, Karl-von-Frisch-Str., 35032 Marburg, Germany

view of species of the European countries (Nast 1987). Meanwhile, check lists or catalogues of Italy (Servadei 1967), the former GDR (Schiemenz 1970), Latvia and Lithuania (Vilbaste 1974), the Netherlands (Gravestein 1976), Poland (Nast 1976), former Czechoslovakia (Dlabola 1977), Greece (Drosopoulos *et al.* 1983, 1986), the British Isles (Le Quesne & Payne 1981), Norway, Sweden, Finland and Denmark (Ossiannilsson 1983) were compiled. Later, check lists of Ireland (de Courcy Williams 1989), Italy (D'Urso 1995), Austria (Holzinger 1996), central Europe (Holzinger *et al.* 1997), Slovenia (Holzinger & Seljak 2001) and Switzerland (Günthart & Mühlethaler 2002) were added.

In Germany, shortly before the political change, Schiemenz (1987, 1988, 1990) had started a compilation of all available faunistic data from the former GDR, which, after his death, was completed by R. Emmrich and W. Witsack (Schiemenz *et al.* 1996). For reunified Germany, Remane & Fröhlich (1994a) presented a check list largely based on their own material as well as on all available literature. Moreover, they clearly distinguished between their own and other data, and between data merely adopted from the literature and those verified by themselves. They also commented on many complicated taxonomic and nomenclatural cases, and specified nonproven records, some of which had been repeated for decades. The number of species considered as verified was 555. Furthermore, 25 "possible" species (adopted from the literature without comment) and 16 dubious species were listed. This paper is also the basis for species interpretation and sequence of supraspecific taxa in the present list.

The present compilation is mainly an ecological and zoogeographic overview, incorporating further extensive material as well as new revisions of literature and museums collections. For the first time, food and host plants, specifications of diet width, life cycle and geographic distribution are given for all species. As a supplement, the most important references as well as the conservation status (Remane *et al.* 1998; Nickel *et al.* 1999) are provided. For newly recorded species, a provisional categorisation of the conservation status is suggested. For the first time, provisional German vernacular names are established, most of which were derived from host plants, habitats or morphology, and which are composed of no more than 4, exceptionally 5 elements. These vernacular names should stimulate interest in this functionally important insect group. Furthermore, translations are necessary for a distinction between species noxious to crops or ornamental plants and those which are harmless.

The following list includes only verified species, although in a few cases, there is some doubt about the correctness of the name and the current taxonomic interpretation. In further cases species limits of some taxa with a high variability of colouration or genital morphology are interpreted as rather wide. For instance, the reddish *Fagocyba cruenta* (H.-S.) is treated as a strongly pigmented summer morph of the yellowish-white *F. douglasi* (Edw.), since most reddish specimens are found singly among large populations of yellowish-white individuals, and a morphological distinction is otherwise impossible. Similarly, we refrain from a separation of the birch-dwelling *Kybos lindbergi* (Lnv.) / *betulicola*- (W.Wg.) complex, which was treated as two distinct species by Dworakowska (1976) and Ossiannilsson (1981), since we found continuous transitions between the two forms. For the same reasons, we treat *Cixius haupti* Dlab. as a younger synonym of *C. beieri* W.Wg., *Edwardsiana staminata* (Rib.) as a younger synonym of *E. avellanae* (Edw.) and *Platymetopius henribauti* Dlab. as a younger synonym of *P. undatus* (De G.). There are also uncertainties regarding the specific status of *Cixius alpestris* W.Wg., *Kelisia nervosa* Vilb., *Macropsis brabantica* W.Wg., *Edwardsiana lanternae* (W.Wg.) and *Doratura littoralis* Kuntze. Finally, after a study of the bulk of central European museum material, we suggest a rather wide interpretation of most tettigometrid species. This opinion takes into account the considerable intraspecific variability of colouration and head shape. A similar variability is also known in *Errhomenus brachypterus* Fieb., the identity of which was clarified only by Lauterer (1983) by a comparative study of large series, and which is also epigeic.

After recent studies of bioacoustics and morphology in the genus *Aphrodes* (Tishechkin 1998), the widely-used interpretation of central European species suggested by Ossiannilson (1981) had to be revised. Furthermore, the *Edwardsiana lethierryi* (Edw.) group has become subject to a revision, producing the original description of the hitherto overlooked *E. ulmiphagus* Wilson & Claridge (1999). Remane & Jung (1995) could demonstrate, that populations of *Kelisia haupti* W.Wg., which were until then considered as a single species, comprised three morphospecies. Thus, they had to describe two new species, which were later also found in southern Germany (Nickel 1999a).

In an achilid species, which for a long time has been treated as *Cixidia marginicollis* (Spin.), no valid name is known at present. Similarly, the commonly used name of *Planaphrodes trifasciata* (Geoffr.) *sensu* Ossiannilsson (1981) is not valid. Hamilton (1975) suggested that the name *P. laeva* (Rey, 1891) had priority, but this still has to be verified by checking Rey's type material. Finally, two new species were described (Remane & Holzinger 1995; Nickel 1999b) and the identity of a dubious species was clarified (Remane & Jung 1995).

We have not quoted old references of species groups, which are subject to new interpretations and thus require a revision of old literature records, for instance, in the genera *Alebra* and *Allygus*. In these cases, as well as in *Aphrodes* and the *Edwardsiana lethierryi* gorup, currently acknowledged species (see Gillham 1991; Ossiannilsson 1983) were not considered by Schiemenz (1990) and Schiemenz *et al.* (1996). Similarly, we refrain from quoting references for species, which were misinterpreted, e.g. in many cases of *Eupteryx collina* (Fl.).

Compared to former check lists, these are only the most important addenda. Together with ecological and zoogeographic specifications and numerous new records mainly from southern Germany (e.g. Lauterer & Malenovský 1995; Remane 1995; Frommer 1996; Heller 1996; Biedermann 1998; Rombach 1999; Nickel & Remane 1996; Nickel 1998, 1999a, 1999b, 2002), they provided reasonable arguments for publishing this new list. For further important annotations and synonyms see Remane & Fröhlich (1994) and Nast (1972), also Nickel (2002) and the end of section 2 of this paper.

2. Species list

Explanations of the list (all specifications exclusively based on data from Germany): Erläuterungen zur Liste (alle Angaben ausschließlich nach Daten aus Deutschland):

Food/host plant: Nomenclature and taxonomy after Wisskirchen & Haeupler (1998)

Annotations:

- 1 Species status uncertain, perhaps conspecific with *C. sticticus* R.
- 2 Preliminary categorization; first recorded in Germany only after publication of the Red Data Book of Auchenorrhyncha (Remane *et al.* 1998).
- 3 Incl. *C. haupti* Dlab.
- 4 Two ecologically clearly distinct forms at the alpine tree limit and in xerothermic sites of middle Germany and the Kaiserstuhl.
- 5 *K. occirega* Remane & Guglielmino, 2002, very recently described from the western half of France, is very similar, but is apparently absent from Germany.
- 6 Species status uncertain, perhaps conspecific with *Kelisia confusa* Lnv.
- 7 The name *K. pannonica* Mats. preferred by Nast (1987) is uncertain. Thus, we prefer Wagner's unambiguous name.
- 8 Ssp. *dehneli* Nast.
- 9 Was published as *Epiptera* (= *Cixidia marginicollis* (Spin.) from the Kaiserstuhl by Wagner & Franz (1961). According to D'Urso & Guglielmino (1995), however, verified records of this species are only known from Sicily. At present, the valid name of south German populations must be considered as uncertain; they may belong to *C. pilatoi* D'Urso & Guglielmino, 1995.
- 10 There are uncertainties about distinction and identity.
- 11 Known from Germany only from the original description (Herrich-Schäffer 1835).
- 12 Until an application is sent to the International Commission of Zoological Nomenclature, the commonly-used name *Tettigometra obliqua* (Panz.) must be treated as a younger synonym. In Germany the species is apparently extinct; the latest verified record dates from 1972.
- 13 This species occurred for a short time on the East Frisian Island of Wangerooge (Harz 1965, 1968).
- 14 In Germany only as a temporary immigrant.
- 15 In Germany there are two bioacoustically distinct forms, which probably belong to distinct species. The nomenclatural situation, however, has yet to be clarified (see Gogala & Trilar 1998, 1999; Gogala 2002).
- 16 Probably extinct, the latest record probably dates back to the 1950s.
- 17 Incl. *N. pallidus* (Hpt.).
- 18 = *Aphrophora alpina* Mel. (Anufriev & Emeljanov 1988; Komatsu 1997)
- 19 = *Aphrophora costalis* Mats. (Komatsu 1997)
- 20 In Germany this taxon probably comprises at least two species (see Claridge & Reynolds 1973; Claridge & Nixon 1986).
- 21 Species group; in Germany there are at least two species.
- 22 Was not distinguished from *Ulmus x hollandica*.
- 23 Species status uncertain. Perhaps indistinguishable from *M. fuscula* (Zett.).
- 24 Perhaps comprises more than one species.
- 25 Syn. nov.: *Idiocerus fuchsii* Kirschbaum, 1868, after a revision of the holotype collected in Switzerland, deposited in MWNH (Naturwissenschaftliche Sammlung des Museums Wiesbaden). – Furthermore, after a revision of the holotype of *I. mesopyrrhus* Kbm., we came to the conclusion that it is conspecific with *T. fulgidus* (F.). This opinion was already published by Wagner (1939), but was ignored by Nast (1972, 1987) and others.
- 26 = *Idiocerus rotundifrons* Ribaut (1952), *nec* Kirschbaum, 1868. This species was properly described and illustrated by Ribaut (1952), but must be given a new name (see below). It is very similar to *A. vittifrons* (Kbm.), but with contrasting, threepart colouration of the dorsal side: head, pronotum and mesonotum light (sometimes yellowish) brown, basal

- two third of wings distinctly reddish brown (often with a metallic tinge, with whitish spot at middle level of the clavus hind margin), apical third pale transparent (*A. vittifrons*: entire dorsal surface marbled more or less evenly pale greyish-brown; fore wings milky transparent also in basal two third; hind margin of clavus distinctly darkened, medially with a whitish spot). ♂ with two narrow, paler brown (instead of one single, broad, blackish-brown) longitudinal bars on postclypeus, reaching only below ocelli (instead of clearly reaching beyond ocelli). Palette only about 1/8 (instead of about 1/3) as long as the filiform part of the antenna. Length: ♂♂ 5,7-6,0 mm; ♀♀ 5,6-6,1 mm; n = 14 (*A. vittifrons*: ♂♂ 5,7-6,0 mm; ♀♀ 5,6-5,9 mm; n = 16). Holotype: ♂, Niedersachsen: Groß Lengden, *Acer campestre*, 20.09.1994; Paratypes: ♀, Mainfranken, Schweinfurt, 12.09.1994; ♂, Mainfranken, St. Ludwig, 24.08.1993; ♀, Niedersachsen: Göttingen, 20.02.1995; all leg. H. Nickel, the two latter deposited in MWNH (Naturwissenschaftliche Sammlung des Museums Wiesbaden).
- 27 = *Idiocerus rotundifrons* Kirschbaum, 1868, after a revision of the holotype in MWNH. This synonymy was already stated by Wagner (1939) who, however, did not draw the nomenclatural consequences.
- 28 *Sensu* Tishechkin (1998), nec Ossiannilsson (1981).
- 29 = *Aphrodes centrorossica* Zachv.
- 30 *Sensu* Ossiannilsson (1981); the valid name has still to be clarified. *P. laeva* (Rey) may have priority (Hamilton 1975).
- 31 Incl. *Kybos betulinola* (W.Wg.) – see Nickel (2002).
- 32 Probably a younger synonym of *E. dealbata* Cer.; furthermore, the relationship with *E. apicalis* (Fl.) described from Latvia and other taxa described from Siberia is critical, since there is considerable intraspecific variation in the shape of the pygophor appendages (see also Remane & Fröhlich 1994b).
- 33 Incl. *Fagocyba douglasii* (Edw.) and *F. inquinata* (Rib.).
- 34 Incl. *Edwardsiana staminata* (Rib.).
- 35 Some authors treat *E. candidula martigniaca* (Cerutti, 1939), which was originally described as a subspecies, as a distinct species (e.g. Nast 1987; P. Lauterer, pers. comm.).
- 36 Are considered as conspecific by some authors.
- 37 = *Edwardsiana hippocastani* (Edw.) (Wilson & Claridge 1999).
- 38 Species status has still to be clarified.
- 39 Has recently been considered as a distinct species (see Lauterer & Novotný 1991).
- 40 Conspecificity of European populations and *E. untica* Dlab. described from elms in Mongolia must be considered as dubious, for zoogeographic and ecological reasons.
- 41 Populations from mountains and lowlands may represent distinct species.
- 42 Possibly conspecific with *Eu. stachydearum* (Hardy).
- 43 Only a single population in a private garden in Stuttgart in August 2001.
- 44 So far only known from greenhouses and their surroundings.
- 45 A distinct species, which is often erroneously treated as a younger synonym of *Z. alpicola* (Cer.), the holotype of which is a ♂ of *Z. mocsaryi* (Horv.) (P. Mazzoglio, pers. comm.), as was already stated by Cerutti (1939).
- 46 From Germany known only from a single specimen, and probably only occurring as a temporary immigrant.
- 47 A single specimen, erroneously published as *Z. nivea* (M. & R.). Immigration is unlikely.
- 48 Populations on Rosaceae and Fagaceae may represent distinct species (Remane 1994).
- 49 At present, distinction and identity are uncertain.
- 50 Some populations belong to *A. potentillae* (Mor.), described from southern Russia. However, it still has to be clarified whether this taxon is a separate species.
- 51 In Germany, known only from a single specimen; perhaps only a temporary immigrant.

- 52 Populations from viticultural regions and the alpine belt of the Alps perhaps belong to different species, the identity of which has still to be clarified .
- 53 Identity and distinction are still unsatisfactorily understood.
- 54 The only German record is the original description dating from 1941 (Wagner 1950). The name *B. lineolata* (Horv.), which has been used for this species until recently, is a younger synonym of *B. punctata* (F.) (Webb & Vilbaste (1994).
- 55 Known from Germany only from the original description (Kirschbaum 1868) and – about 130 years later – a few temporary immigrants (Nickel 1999b).
- 56 Distinction of some populations is critical.
- 57 Perhaps only a colour morph of *D. homophyla* (Fl.).
- 58 Incl. *P. henribauti* Dlab.
- 59 Comprises probably at least two species, which are morphologically and ecologically distinct.
- 60 Erroneously published as *C. intermedia* (Boh.) (Schiemenz *et al.* 1996).
- 61 The occurrence of other species of the genus *Ophiola* in Germany, notably *O. plutonia* (Uhl.) and *O. ocellaris* (Leth.), still have to be verified.
- 62 Perhaps a younger synonym of *S. ogumae* (Mats.), although a type revision of the latter still has to be done.
- 63 Populations of central European inland salt meadows (westward at least to the upper Rhine) are slightly, but significantly distinct from those from coastal regions. They are indistinguishable from eastern European populations published as *P. major* Hpt. (Nickel 2002). However, clarification is still required as to whether these are conspecific with the holotype described from Palestine.
- 64 The correct name is uncertain.
- 65 The only record from Germany dates from 1964.
- 66 In Germany, there are at least two distinguishable forms, which were provisionally described as "hevolus basic" (in warmer lowlands, up to c. 800 m) and "hevolus acidic" (in cooler and higher altitudes, not below 300 m) (Remane 1987).
- 67 Morphological distinction of species in this group is critical.
- 68 Syn. nov.: *Psammotettix remanei* Orosz, 1999. Was recently described from Hungary, with paratypes collected in the Oberlausitz (Saxony). However, the types are teratologic individuals with only partially developed genital apparatus. This is particularly true for the genital plates, lateral pygophor lobes, basis and shaft of the aedeagus, as well as the connective, which is rather anomalous for the whole tribe of Paralimnini. Furthermore, they show a reduction of body size and pigmentation, although clear symptoms of parasitization (e.g. by Pipunculidae or Strepsiptera) are visible only in a few cases. Such individuals of *P. confinis* (Dhlb.) are frequently found in many populations throughout central Europe.
- 69 Syn. nov.: *Deltoccephalus antennalis* Haupt, 1924. After a type revision of *Jassus leucophaeus* Kirschbaum, 1868 (MWNH) from the Swiss Vorderrhein we found that both taxa are conspecific.
- 70 Incl. *J. bavaricus* (Rib.).

3. Dubious species

A number of species, which have until recently been listed for Germany (e.g. Nast 1987), are considered here as dubious. In some cases there are uncertainties regarding their species status or distinction. Other species, the identity of which is clear, could be found neither in museum collections nor in the field, despite directed search during recent years, and therefore,

should no longer be cited or listed (see also Nickel 2002). Some of these were demonstrably based on incorrect citations of other references, or the origin of specimens is dubious:

<i>Ribautodelphax pallens</i> (Stål)	<i>Chlorita viridula</i> (Fall.)
<i>Tettigometra concolor</i> Fieb.	<i>Edwardsiana kemneri</i> (Oss.)
<i>Micrometrina longicornis</i> Sign.	<i>Zygina rhamni</i> Ferr.
<i>Ommatidiotus concinnus</i> Horv.	<i>Macrosteles empetri</i> (Oss.)
<i>Phantia subquadrata</i> (H.-S.)	<i>Macrosteles nubilus</i> (Oss.)
<i>Cercopis intermedia</i> Kbm.	<i>Selenocephalus obsoletus</i> (Germ.)
<i>Ulopa lugens</i> Germ.	<i>Handianus procerus</i> (H.-S.)
<i>Metidiocerus fasciatus</i> (Fieb.)	<i>Handianus flavovarius</i> (H.-S.)
<i>Paradorydium paradoxum</i> (H.-S.)	<i>Psammotettix ornaticeps</i> (Horv.)
<i>Dikranura aridella</i> (J. Shlb.)	<i>Diplocolenus frauensfeldi</i> (Fieb.)

4. Discussion and concluding remarks

Accordingly, altogether 620 species are reliably documented for Germany, although in a few cases there are uncertainties concerning the correct name. In each of the recent decades, between 12 and 43 new species have been recorded in the field, through revisions or new original descriptions. The true species number should therefore clearly exceed 650 and perhaps even 700, since an attenuation of the increase in species numbers is not yet evident (Fig. 1). Thus, in the near future, a number of new species to Germany should be recorded, which are known to occur in adjacent regions of neighbouring countries, such as the Mediterranean *Asymmetrasca decedens* (Paoli), *Synophropsis lauri* (Horv.) and *Goldeus harpago* (Rib.) and the neozoa *Kyboasca maligna* (Walsh) from North America and the east Asian *Orientus ishidae* (Mats.) (see Baugnée 1995; della Giustina & Remane 2001; Mühlethaler 2001; Günthart & Mühlethaler 2002). Further new species records can be expected from the Bavarian and Allgäu Alps, from southwestern viticultural regions, and perhaps from eastern parts (mainly Mecklenburg, Brandenburg) and the extreme west (Moselle valley, Eifel Mountains). In contrast, the probability of new species being recorded in northern Germany is rather small, for biogeographic reasons and due to intensive former collecting activity (notably by W. Wagner and R. Remane).

At least 6 species are listed here that must provisionally be considered as temporary immigrants without permanent reproductive success: *Toya propinqua* (Fieb.), *Agalmatium bilobum* (Fieb.), *Cicada orni* L., *Zyginidia pullula* (Boh.), *Fruticidia sanguinosa* (R.) and *Balclutha saltuella* (Kbm.). Four species are neozoa: *Stictocephala bisonia* Kopp & Yonke (Buffalo treehopper) and *Graphocephala fennahi* Young (Rhododendron leafhopper) both originate from North America; *Macropsis elaeagni* Em. originates from middle Asia; the mediterranean *Hauptidia provincialis* (Rib.) was recorded in a south German greenhouse, but it is not yet clear whether the colonisation will be permanent. It is also uncertain, whether *Japananus hyalinus* (Osb.) was introduced from eastern Asia, as was commonly suggested in the literature. This must be considered as highly speculative, considering the fact that its main host plant, *Acer campestre*, is native to Europe, and because it commonly occurs in near-natural habitats. In other cases, introduction or at least anthropogenic benefiting is likely, for instance in some mediterranean species of the genus *Eupteryx* living on members of the Lamiaceae. These species are widespread in central European herbal gardens, but are absent from near-natural sites, e.g. *E. decemnotata* R. and *E. melissae* Curt. Very recently, *E. salviae* Arz. & Vid. was recorded for the first time.

Fig. 2 shows an overview of the taxonomic affiliations of recorded species. The Cicadomorpha account for about three quarters (452 species alone belong to the Cicadellidae) and the Fulgoromorpha account for only one quarter. Highest numbers are found in Deltocephalinae (194 species, 31%), followed by Typhlocybinae (158 species, 25%) and Delphacidae (109

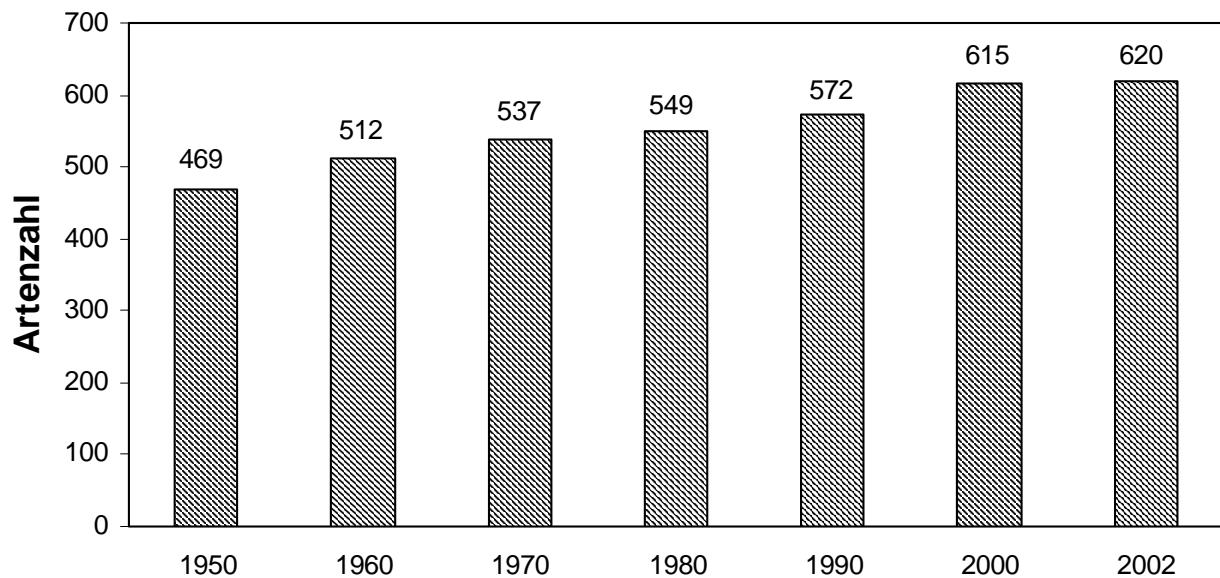

Fig. 1: Numbers of Auchenorrhyncha species known from Germany since 1950. Additional records were counted at the time of the first record or after the publication of taxonomic revisions and original descriptions, respectively. — Summen der Zikadenartennachweise in Germany seit 1950. Neuzugänge wurden gewertet zum Zeitpunkt des ersten Nachweises bzw. nach dem Erscheinen von Revisionen und Neubeschreibungen.

species, 18%). Cixiidae, Cercopidae (spittle bugs), Macropsinae, Idiocerinae and Aphrodinae are each represented by 10 to 30 species. In the remaining groups, notably in Achilidae, Dictyopharidae, Issidae, Tettigometridae, Cicadidae (cicadas), Membracidae (tree hoppers) and the remaining cicadellid subgroups, species numbers are only below 10.
