D05BEF - NAG Fortran Library Routine Document

Note. Before using this routine, please read the Users' Note for your implementation to check the interpretation of bold italicised terms and other implementation-dependent details.

1 Purpose

D05BEF computes the solution of a weakly singular nonlinear convolution Volterra—Abel integral equation of the first kind using a fractional Backward Differentiation Formulae (BDF) method.

2 Specification

SUBROUTINE DO5BEF(CK, CF, CG, INITWT, IORDER, TLIM, TOLNL, NMESH,

YN, WORK, LWK, NCT, IFAIL)

INTEGER IORDER, NMESH, LWK, NCT(NMESH/32+1), IFAIL

real CK, CF, CG, TLIM, TOLNL, YN(NMESH), WORK(LWK)

CHARACTER*1 INITWT

EXTERNAL CK, CF, CG

3 Description

D05BEF computes the numerical solution of the weakly singular convolution Volterra–Abel integral equation of the first kind

$$f(t) + \frac{1}{\sqrt{\pi}} \int_0^t \frac{k(t-s)}{\sqrt{t-s}} g(s, y(s)) \, ds = 0, \quad 0 \le t \le T.$$
 (1)

Note the constant $\frac{1}{\sqrt{\pi}}$ in (1). It is assumed that the functions involved in (1) are sufficiently smooth and if

$$f(t) = t^{\beta}w(t) \text{ with } \beta > -\frac{1}{2}, \tag{2}$$

then the solution y(t) is unique and has the form $y(t) = t^{\beta - 1/2}z(t)$, (see [4]). It is evident from (1) that f(0) = 0. The user is required to provide the value of y(t) at t = 0. If y(0) is unknown, Section 8 gives a description of how an approximate value can be obtained.

The routine uses a fractional BDF linear multi-step method selected by the user to generate a family of quadrature rules (see D05BYF). The BDF methods available in D05BEF are of orders 4, 5 and 6 (= p say). For a description of the theoretical and practical background related to these methods we refer to [4] and [1],[3] respectively.

The algorithm is based on computing the solution y(t) in a step-by-step fashion on a mesh of equispaced points. The size of the mesh is given by T/(N-1), N being the number of points at which the solution is sought. These methods require 2p-2 starting values which are evaluated internally. The computation of the lag term arising from the discretization of (1) is performed by fast Fourier transform (FFT) techniques when N > 32 + 2p - 1, and directly otherwise. The routine does not provide an error estimate and users are advised to check the behaviour of the solution with a different value of N. An option is provided which avoids the re-evaluation of the fractional weights when D05BEF is to be called several times (with the same value of N) within the same program with different functions.

5 Parameters

1: CK - real FUNCTION, supplied by the user.

External Procedure

CK must evaluate the kernel k(t) of the integral equation (1).

Its specification is:

 $egin{array}{ll} real & ext{FUNCTION CK(T)} \\ real & ext{T} \end{array}$

1: T-real

Input

On entry: the value of the independent variable, t.

CK must be declared as EXTERNAL in the (sub)program from which D05BEF is called. Parameters denoted as *Input* must **not** be changed by this procedure.

2: CF - real FUNCTION, supplied by the user.

External Procedure

CF must evaluate the function f(t) in (1).

Its specification is:

 $egin{array}{ll} real & ext{FUNCTION CF(T)} \\ real & ext{T} \end{array}$

1: T-real

Input

On entry: the value of the independent variable, t.

CF must be declared as EXTERNAL in the (sub)program from which D05BEF is called. Parameters denoted as *Input* must **not** be changed by this procedure.

3: CG - real FUNCTION, supplied by the user.

External Procedure

CG must evaluate the function g(s, y(s)) in (1).

Its specification is:

real FUNCTION CG(S, Y) real S, Y

1: S-real

Input

On entry: the value of the independent variable, s.

Y-real

Input

On entry: the value of the solution y at the point s.

CG must be declared as EXTERNAL in the (sub)program from which D05BEF is called. Parameters denoted as *Input* must **not** be changed by this procedure.

D05BEF.2 [NP3390/19/pdf]

4: INITWT — CHARACTER*1

Input

On entry: if the fractional weights required by the method need to be calculated by the routine, then set INITWT = 'I' (Initial call).

If INITWT = 'S' (Subsequent call), then the routine assumes the fractional weights have been computed by a previous call and are stored in WORK.

Constraint: INITWT = 'I' or 'S'.

Note: When D05BEF is re-entered with a value of INITWT = 'S', the values of NMESH, IORDER and the contents of WORK **must** not be changed.

5: IORDER — INTEGER

Input

On entry: the order of the BDF method to be used, p.

Constraint: $4 \leq IORDER \leq 6$.

Suggested value: IORDER = 4.

6: TLIM — real

On entry: the final point of the integration interval, T.

Constraint: TLIM > $10 \times machine\ precision$.

7: TOLNL - real Input

On entry: the accuracy required for the computation of the starting value and the solution of the nonlinear equation at each step of the computation (see Section 8).

Constraint: TOLNL > $10 \times machine\ precision$.

Suggested value: TOLNL = $\sqrt{\epsilon}$ where ϵ is the **machine precision**.

8: NMESH — INTEGER

Input

On entry: the number of equispaced points, N, at which the solution is sought.

Constraint: NMESH = $2^m + 2 \times IORDER - 1$, where $m \ge 1$.

9: YN(NMESH) - real array

Input/Output

On entry: YN(1) must contain the value of y(t) at t = 0 (see Section 8).

On exit: YN(i) contains the approximate value of the true solution y(t) at the point $t = (i-1) \times h$, for i = 1,2,...,NMESH, where h = TLIM/(NMESH-1).

10: WORK(LWK) — real array

Workspace

11: LWK — INTEGER

Input

On entry: the dimension of the array WORK as declared in the (sub)program from which D05BEF is called.

Constraint: LWK $\geq (2 \times IORDER + 6) \times NMESH + 8 \times IORDER^2 - 16 \times IORDER + 1$.

12: NCT(NMESH/32+1) — INTEGER array

Work space

13: IFAIL — INTEGER

Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in Chapter P01) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

Errors detected by the routine:

IFAIL = 1

On entry, ORDER < 4 or IORDER 6,

or TLIM $\leq 10 \times machine\ precision$,

or INITWT \neq 'I' or 'S',

or INITWT = 'S' on the first call to D05BEF,

or TOLNL $\leq 10 \times machine\ precision$,

or NMESH $\neq 2^m + 2 \times IORDER -1, m \geq 1$,

or LWK $< (2 \times IORDER + 6) \times NMESH + 8 \times IORDER^2 - 16 \times IORDER + 1$.

IFAIL = 2

The routine cannot compute the 2p-2 starting values due to an error in solving the system of nonlinear equations. Relaxing the value of TOLNL and/or increasing the value of NMESH may overcome this problem (see Section 8 for further details).

IFAIL = 3

The routine cannot compute the solution at a specific step due to an error in the solution of single nonlinear equation (3). Relaxing the value of TOLNL and/or increasing the value of NMESH may overcome this problem (see Section 8 for further details).

7 Accuracy

The accuracy depends on NMESH and TOLNL, the theoretical behaviour of the solution of the integral equation and the interval of integration. The value of TOLNL controls the accuracy required for computing the starting values and the solution of (3) at each step of computation. This value can affect the accuracy of the solution. However, for most problems, the value of $\sqrt{\epsilon}$, where ϵ is the **machine precision**, should be sufficient.

In general, for the choice of BDF method, the user is recommended to use the fourth-order BDF formula (i.e., IORDER = 4).

8 Further Comments

Also when solving (1) the initial value y(0) is required. This value may be computed from the limit relation (see [2])

$$\frac{-2}{\sqrt{\pi}}k(0)g(0,y(0)) = \lim_{t \to 0} \frac{f(t)}{\sqrt{t}}.$$
 (3)

If the value of the above limit is known then by solving the nonlinear equation (3) an approximation to y(0) can be computed. If the value of the above limit is not known, an approximation should be provided. Following the analysis presented in [2], the following pth-order approximation can be used:

$$\lim_{t \to 0} \frac{f(t)}{\sqrt{t}} \simeq \frac{f(h^P)}{h^{P/2}}.$$
 (4)

However, it must be emphasized that the approximation in (4) may result in an amplification of the rounding errors and hence users are advised (if possible) to determine $\lim_{t\to 0} \frac{f(t)}{\sqrt{t}}$ by analytical methods.

Also when solving (1), initially, D05BEF computes the solution of a system of nonlinear equation for obtaining the 2p-2 starting values. C05NDF is used for this purpose. If a failure with IFAIL = 2 occurs (corresponding to an error exit from C05NDF), users are advised to either relax the value of TOLNL

D05BEF.4 [NP3390/19/pdf]

or choose a smaller step size by increasing the value of NMESH. Once the starting values are computed successfully, the solution of a nonlinear equation of the form

$$Y_n - \alpha g(t_n, Y_n) - \Psi_n = 0, \tag{5}$$

is required at each step of computation, where Ψ_n and α are constants. D05BEF calls C05AXF to find the root of this equation.

When a failure with IFAIL = 3 occurs (which corresponds to an error exit from C05AXF), users are advised to either relax the value of the TOLNL or choose a smaller step size by increasing the value of NMESH.

If a failure with IFAIL = 2 or 3 persists even after adjustments to TOLNL and/or NMESH then the user should consider whether there is a more fundamental difficulty. For example, the problem is ill-posed or the functions in (1) are not sufficiently smooth.

9 Example

We solve the following integral equations.

Example 1:

The density of the probability that a Brownian motion crosses a one-sided moving boundary a(t) before time t, satisfies the integral equation (see [3])

$$-\frac{1}{\sqrt{t}}\exp\left(\frac{1}{2} - \{a(t)\}^2/t\right) + \int_0^t \frac{\exp\left(-\frac{1}{2}\{a(t) - a(s)\}^2/(t-s)\right)}{\sqrt{t-s}}y(s) \, ds = 0, \quad 0 \le t \le 7.$$

In the case of a straight line a(t) = 1 + t, the exact solution is known to be

$$y(t) = \frac{1}{\sqrt{2\pi t^3}} \exp\{-(1+t)^2/2t\}$$

Example 2:

In this example we consider the equation

$$-\frac{2\log(\sqrt{1+t}+\sqrt{t})}{\sqrt{1+t}} + \int_0^t \frac{y(s)}{\sqrt{t-s}} ds = 0, \ \ 0 \le t \le 5.$$

The solution is given by $y(t) = \frac{1}{1+t}$.

INTEGER

In the above examples, the fourth-order BDF is used, and NMESH is set to $2^6 + 7$.

9.1 Program Text

Note. The listing of the example program presented below uses bold italicised terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
