E01AEF - NAG Fortran Library Routine Document

Note. Before using this routine, please read the Users' Note for your implementation to check the interpretation of bold italicised terms and other implementation-dependent details.

1 Purpose

E01AEF constructs the Chebyshev-series representation of a polynomial interpolant to a set of data which may contain derivative values.

2 Specification

SUBROUTINE E01A	EF(M, XMIN, XMAX, X, Y, IP, N, ITMIN, ITMAX, A,
1	WRK, LWRK, IWRK, LIWRK, IFAIL)
INTEGER	M, IP(M), N, ITMIN, ITMAX, LWRK, IWRK(LIWRK),
1	LIWRK, IFAIL
real	XMIN, XMAX, X(M), Y(N), A(N), WRK(LWRK)

3 Description

Let *m* distinct values x_i of an independent variable *x* be given, with $x_{\min} \le x_i \le x_{\max}$, for i = 1, 2, ..., m. For each value x_i , suppose that the value y_i of the dependent variable *y* together with the first p_i derivatives of *y* with respect to *x* are given. Each p_i must therefore be a non-negative integer, with the

total number of interpolating conditions, n, equal to $m + \sum_{i=1}^{m} p_i$.

E01AEF calculates the unique polynomial q(x) of degree n-1 (or less) which is such that $q^{(k)}(x_i) = y_i^{(k)}$ for i = 1, 2, ..., m; $k = 0, 1, ..., p_i$. Here $q^{(0)}(x_i)$ means $q(x_i)$. This polynomial is represented in Chebyshev-series form in the normalised variable \bar{x} , as follows:

$$q(x) = \frac{1}{2}a_0T_0(\bar{x}) + a_1T_1(\bar{x}) + \ldots + a_{n-1}T_{n-1}(\bar{x}),$$

where

$$r = \frac{2x - x_{\min} - x_{\max}}{x_{\max} - x_{\min}}$$

so that $-1 \leq \bar{x} \leq 1$ for x in the interval x_{\min} to x_{\max} , and where $T_i(\bar{x})$ is the Chebyshev polynomial of the first kind of degree i with argument \bar{x} .

(The polynomial interpolant can subsequently be evaluated for any value of x in the given range by using E02AKF. Chebyshev-series representations of the derivative(s) and integral(s) of q(x) may be obtained by (repeated) use of E02AHF and E02AJF.)

The method used consists first of constructing a divided-difference table from the normalised \bar{x} values and the given values of y and its derivatives with respect to \bar{x} . The Newton form of q(x) is then obtained from this table, as described in Huddleston [1] and Krogh [2], with the modification described in Section 8.2. The Newton form of the polynomial is then converted to Chebyshev-series form as described in Section 8.3.

Since the errors incurred by these stages can be considerable, a form of iterative refinement is used to improve the solution. This refinement is particularly useful when derivatives of rather high order are given in the data. In reasonable examples, the refinement will usually terminate with a certain accuracy criterion satisfied by the polynomial (see Section 7). In more difficult examples, the criterion may not be satisfied and refinement will continue until the maximum number of iterations (as specified by the input parameter ITMAX) is reached.

In extreme examples, the iterative process may diverge (even though the accuracy criterion is satisfied): if a certain divergence criterion is satisfied, the process terminates at once. In all cases the routine returns the 'best' polynomial achieved before termination. For the definition of 'best' and details of iterative refinement and termination criteria, see Section 8.4.

5 Parameters

1: M — INTEGER

On entry: m, the number of given values of the independent variable x.

Constraint: $M \ge 1$.

2: XMIN — real

3: XMAX — real

On entry: the lower and upper end-points, respectively, of the interval $[x_{\min}, x_{\max}]$. If they are not determined by the user's problem, it is recommended that they be set respectively to the smallest and largest values among the x_i .

Constraint: XMIN < XMAX.

4: X(M) - real array

On entry: the value of x_i , for i = 1, 2, ..., m. The X(i) need not be ordered.

Constraint: XMIN $\leq X(i) \leq XMAX$, and the X(i) must be distinct.

5: Y(N) - real array

On entry: the given values of the dependent variable, and derivatives, as follows:

The first $p_1 + 1$ elements contain $y_1, y_1^{(1)}, \ldots, y_1^{(p_1)}$ in that order.

The next $p_2 + 1$ elements contain $y_2, y_2^{(1)}, \dots, y_2^{(p_2)}$ in that order.

•••

The last $p_m + 1$ elements contain $y_m, y_m^{(1)}, \dots, y_m^{(p_m)}$ in that order.

6: IP(M) — INTEGER array

On entry: p_i , the order of the highest-order derivative whose value is given at x_i , for i = 1, 2, ..., m. If the value of y only is given for some x_i then the corresponding value of IP(i) must be zero.

Constraint: $IP(i) \ge 0$, for $i = 1, 2, \dots, M$.

7: N — INTEGER

On entry: the total number of interpolating conditions, n.

Constraint: $N = M + IP(1) + IP(2) + \ldots + IP(M)$.

8: ITMIN — INTEGER

9: ITMAX — INTEGER

On entry: respectively the minimum and maximum number of iterations to be performed by the routine (for full details see Section 8.4, second paragraph). Setting ITMIN and/or ITMAX negative or zero invokes default value(s) of 2 and/or 10, respectively.

The default values will be satisfactory for most problems, but occasionally significant improvement will result from using higher values.

Suggested value: ITMIN = 0 and ITMAX = 0.

Input

Input

Input

Input

Input

Input

Input

Input Input

10: A(N) - real array

On exit: A(i) contains the coefficient a_{i-1} in the Chebyshev-series representation of q(x), for i = 1, 2, ..., n.

11: WRK(LWRK) — *real* array
Used as workspace, but see also Section 8.5.

12: LWRK — INTEGER

 $On\ entry:$ the dimension of the array WRK as declared in the (sub)program from which E01AEF is called.

Constraint: LWRK $\geq 7 \times N + 5 \times IPMAX + M + 7$, where IPMAX is the largest value of IP(i), for i = 1, 2, ..., M.

13: IWRK(LIWRK) — INTEGER array

Used as workspace, but see also Section 8.5.

14: LIWRK — INTEGER

 $On\ entry:$ the dimension of the array IWRK as declared in the (sub)program from which E01AEF is called.

Constraint: LIWRK $\geq 2 \times M + 2$.

15: IFAIL — INTEGER

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in Chapter P01) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

Errors detected by the routine:

IFAIL = 1

On entry, M < 1, or $N \neq M + IP(1) + IP(2) + \ldots + IP(M)$, or LWRK < 7 × N + 5 × IPMAX + M + 7, or LIWRK < 2 × M + 2

(IPMAX is defined under LWRK).

 $\mathrm{IFAIL}=2$

On entry, IP(i) < 0 for some *i*.

$$IFAIL = 3$$

On entry, $XMIN \ge XMAX$, or X(i) < XMIN for some i, or X(i) > XMAX,

or X(i) = X(j) for some $i \neq j$.

IFAIL = 4

Not all the performance indices are less than eight times the *machine precision*, although ITMAX iterations have been performed. Parameters A, WRK and IWRK relate to the best polynomial determined. A more accurate solution may possibly be obtained by increasing ITMAX and recalling the routine. See also Section 7, Section 8.4 and Section 8.5.

E01AEF.3

Output

Input

Workspace

Workspace

Input/Output

Input

IFAIL = 5

The computation has been terminated because the iterative process appears to be diverging. (Parameters A, WRK and IWRK relate to the best polynomial determined.) Thus the problem specified by the user's data is probably too ill-conditioned for the solution to be satisfactory. This may result from some of the X(i) being very close together, or from the number of interpolating conditions, N, being large. If in such cases the conditions do not involve derivatives, the user is likely to obtain a much more satisfactory solution to his problem either by cubic spline interpolation (see E01BAF) or by curve fitting with a polynomial or spline in which the number of coefficients is less than N, preferably much less if N is large (see the E02 Chapter Introduction). But see Section 7 and Section 8.4–Section 8.5.

7 Accuracy

A complete error analysis is not currently available, but the method gives good results for reasonable problems.

It is important to realise that for some sets of data, the polynomial interpolation problem is **ill-conditioned**. That is, a **small** perturbation in the data may induce **large** changes in the polynomial, **even in exact arithmetic**. Though by no means the worst example, interpolation by a single polynomial to a large number of function values given at points equally spaced across the range is notoriously ill-conditioned and the polynomial interpolating such a data set is prone to exhibit enormous oscillations between the data points, especially near the ends of the range. These will be reflected in the Chebyshev coefficients being large compared with the given function values. A more familiar example of ill-conditioning occurs in the solution of certain systems of linear algebraic equations, in which a small change in the elements of the matrix and/or in the components of the right-hand side vector induces a relatively large change in the solution vector. The best that can be achieved in these cases is to make the residual vector small in some sense. If this is possible, the computed solution is exact for a slightly perturbed set of data. Similar considerations apply to the interpolation problem.

The residuals $y_i^{(k)} - q^{(k)}(x_i)$ are available for inspection (see Section 8.5). To assess whether these are reasonable, however, it is necessary to relate them to the largest function and derivative values taken by q(x) over the interval $[x_{\min}, x_{\max}]$. The following performance indices aim to do this. Let the *k*th derivative of q with respect to the normalised variable \bar{x} be given by the Chebyshev-series

$$\frac{1}{2}a_0^k T_0(\bar{x}) + a_1^k T_1(\bar{x}) + \ldots + a_{n-1-k}^k T_{n-1-k}(\bar{x}).$$

Let A_k denote the sum of the moduli of these coefficients (this is an upper bound on the kth derivative in the interval and is taken as a measure of the maximum size of this derivative), and define

$$S_k = \max_{i \le k} A_i.$$

Then if the root-mean-square value of the residuals of $q^{(k)}$, scaled so as to relate to the normalised variable \bar{x} , is denoted by r_k , the performance indices are defined by

$$P_k = r_k / S_k$$
, for $k = 0, 1, \dots, \max_i (p_i)$.

It is expected that, in reasonable cases, they will all be less than (say) 8 times the *machine precision* (this is the accuracy criterion mentioned in Section 3), and in many cases will be of the order of *machine precision* or less.

8 Further Comments

8.1 Timing

Computation time is approximately proportional to $IT \times n^3$, where IT is the number of iterations actually used. (See Section 8.5).

8.2 Divided-difference Strategy

In constructing each new coefficient in the Newton form of the polynomial, a new x_i must be brought into the computation. The x_i chosen is that which yields the smallest new coefficient. This strategy increases the stability of the divided-difference technique, sometimes quite markedly, by reducing errors due to cancellation.

8.3 Conversion to Chebyshev Form

Conversion from the Newton form to Chebyshev-series form is effected by evaluating the former at the n values of \bar{x} at which $T_{n-1}(x)$ takes the value ± 1 , and then interpolating these n function values by a call of E02AFF, which provides the Chebyshev-series representation of the polynomial with very small additional relative error.

8.4 Iterative Refinement

The iterative refinement process is performed as follows. First, an initial approximation, $q_1(x)$ say, is found by the technique described above. The *r*th step of the refinement process then consists of evaluating the residuals of the *r*th approximation $q_r(x)$, and constructing an interpolant, $dq_r(x)$, to these residuals. The next approximation $q_{r+1}(x)$ to the interpolating polynomial is then obtained as

$$q_{r+1}(x) = q_r(x) + dq_r(x).$$

This completes the description of the rth step.

The iterative process is terminated according to the following criteria. When a polynomial is found whose performance indices (as defined in Section 7) are all less than 8 times the **machine precision**, the process terminates after ITMIN further iterations (or after a total of ITMAX iterations if that occurs earlier). This will occur in most reasonable problems. The extra iterations are to allow for the possibility of further improvement. If no such polynomial is found, the process terminates after a total of ITMAX iterations. Both these criteria are over-ridden, however, in two special cases. Firstly, if for some value of r the sum of the moduli of the Chebyshev coefficients of $dq_r(x)$ is greater than that of $q_r(x)$, it is concluded that the process is diverging and the process is terminated at once $(q_{r+1}(x)$ is not computed). Secondly, if at any stage, the performance indices are all computed as zero, again the process is terminated at once.

As the iterations proceed, a record is kept of the best polynomial. Subsequently, at the end of each iteration, the new polynomial replaces the current best polynomial if it satisfies two conditions (otherwise the best polynomial remains unchanged). The first condition is that at least one of its root-mean-square residual values, r_k (see Section 7) is smaller than the corresponding value for the current best polynomial. The second condition takes two different forms according to whether or not the performance indices (see Section 7) of the current best polynomial are all less than 8 times the *machine precision*. If they are, then the largest performance index of the new polynomial is required to be less than that of the current best polynomial. If they are not, the number of indices which are less than 8 times *machine precision* must not be smaller than for the current best polynomial. When the iterative process is terminated, it is the polynomial then recorded as best, which is returned to the user as q(x).

8.5 Workspace Information

On successful exit, and also if IFAIL = 4 or 5 on exit, the following information is contained in the workspace arrays WRK and IWRK:

WRK(k+1), for $k = 0, 1, \ldots$, IPMAX where IPMAX = $\max_{i} p_i$, contains the ratio of p_k , the performance index relating to the kth derivative of the q(x) finally provided, to 8 times the **machine precision**.

WRK(IPMAX+1+j), for j = 1, 2, ..., n, contains the *j*th residual, i.e., the value of $y_i^{(k)} - q^{(k)}(x_i)$, where *i* and *k* are the appropriate values corresponding to the *j*th element in the array Y (see description of Y in Section 5).

IWRK(1) contains the number of iterations actually performed in deriving q(x).

If, on exit, IFAIL = 4 or 5, the q(x) finally provided may still be adequate for the user's requirements. To assess this the user should examine the residuals contained in WRK(IPMAX+1+j), for j = 1, 2, ..., n, to see whether they are acceptably small.

9 Example

To construct an interpolant q(x) to the following data:

$$\begin{array}{ll} m=4, & x_{\min}=2, & x_{\max}=6, \\ x_1=2, & p_1=0, & y_1=1, \\ x_2=4, & p_2=1, & y_2=2, & y_2^{(1)}=-1, \\ x_3=5, & p_3=0, & y_3=1, \\ x_4=6, & p_4=2, & y_4=2, & y_4^{(1)}=4, & y_4^{(2)}=-2. \end{array}$$

The coefficients in the Chebyshev-series representation of q(x) are printed, and also the residuals corresponding to each of the given function and derivative values.

This program is written in a generalised form which can read any number of data-sets.

9.1 Program Text

Note. The listing of the example program presented below uses bold italicised terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
