F07MSF (CHETRS/ZHETRS) - NAG Fortran Library Routine Document

Note. Before using this routine, please read the Users' Note for your implementation to check the interpretation of bold italicised terms and other implementation-dependent details.

1 Purpose

F07MSF (CHETRS/ZHETRS) solves a complex Hermitian indefinite system of linear equations with multiple right-hand sides, AX = B, where A has been factorized by F07MRF (CHETRF/ZHETRF).

2 Specification

```
SUBROUTINE FO7MSF(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
ENTRY chetrs(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
INTEGER N, NRHS, LDA, IPIV(*), LDB, INFO
complex
CHARACTER*1 UPLO
```

The ENTRY statement enables the routine to be called by its LAPACK name.

3 Description

To solve a complex Hermitian indefinite system of linear equations AX = B, this routine must be preceded by a call to F07MRF (CHETRF/ZHETRF) which computes the Bunch–Kaufman factorization of A.

If UPLO = 'U', $A = PUDU^H P^T$, where P is a permutation matrix, U is an upper triangular matrix and D is an Hermitian block diagonal matrix with 1 by 1 and 2 by 2 blocks; the solution X is computed by solving PUDY = B and then $U^H P^T X = Y$.

If UPLO = 'L', $A = PLDL^HP^T$, where L is a lower triangular matrix; the solution X is computed by solving PLDY = B and then $L^HP^TX = Y$.

5 Parameters

1: UPLO — CHARACTER*1

Input

On entry: indicates how A has been factorized as follows:

```
if UPLO = 'U', then A = PUDU^H P^T, where U is upper triangular; if UPLO = 'L', then A = PLDL^H P^T, where L is lower triangular.
```

Constraint: UPLO = 'U' or 'L'.

2: N — INTEGER

Input

On entry: n, the order of the matrix A.

Constraint: $N \geq 0$.

3: NRHS — INTEGER

Input

On entry: r, the number of right-hand sides.

Constraint: NRHS ≥ 0 .

4: A(LDA,*) — complex array

Input

Note: the second dimension of the array A must be at least max(1,N).

On entry: details of the factorization of A, as returned by F07MRF (CHETRF/ZHETRF).

5: LDA — INTEGER

Input

On entry: the first dimension of the array A as declared in the (sub)program from which F07MSF (CHETRS/ZHETRS) is called.

Constraint: LDA $\geq \max(1,N)$.

6: IPIV(*) — INTEGER array

Input

Note: the dimension of the array IPIV must be at least max(1,N).

On entry: details of the interchanges and the block structure of D, as returned by F07MRF (CHETRF/ZHETRF).

7: B(LDB,*) - complex array

Input/Output

Note: the second dimension of the array B must be at least max(1,NRHS).

On entry: the n by r right-hand side matrix B.

On exit: the n by r solution matrix X.

8: LDB — INTEGER

Input

On entry: the first dimension of the array B as declared in the (sub)program from which F07MSF (CHETRS/ZHETRS) is called.

Constraint: LDB $\geq \max(1,N)$.

9: INFO — INTEGER

Output

On exit: INFO = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

INFO < 0

If INFO = -i, the *i*th parameter had an illegal value. An explanatory message is output, and execution of the program is terminated.

7 Accuracy

For each right-hand side vector b, the computed solution x is the exact solution of a perturbed system of equations (A + E)x = b, where

$$\begin{split} |E| &\leq c(n)\epsilon P|U||D||U^H|P^T \quad \text{ifUPLO} = \text{'U'}, \\ |E| &\leq c(n)\epsilon P|L||D||L^H|P^T \quad \text{ifUPLO} = \text{'L'}, \end{split}$$

c(n) is a modest linear function of n, and ϵ is the $machine\ precision$.

If \hat{x} is the true solution, then the computed solution x satisfies a forward error bound of the form

$$\frac{\|x - \hat{x}\|_{\infty}}{\|x\|_{\infty}} \le c(n) \operatorname{cond}(A, x) \epsilon$$

where $\operatorname{cond}(A,x) = \| |A^{-1}||A||x| \|_{\infty}/\|x\|_{\infty} \leq \operatorname{cond}(A) = \| |A^{-1}||A| \|_{\infty} \leq \kappa_{\infty}(A)$. Note that $\operatorname{cond}(A,x)$ can be much smaller than $\operatorname{cond}(A)$.

Forward and backward error bounds can be computed by calling F07MVF (CHERFS/ZHERFS), and an estimate for $\kappa_{\infty}(A)$ (= $\kappa_{1}(A)$) can be obtained by calling F07MUF (CHECON/ZHECON).

8 Further Comments

The total number of real floating-point operations is approximately $8n^2r$.

This routine may be followed by a call to F07MVF (CHERFS/ZHERFS) to refine the solution and return an error estimate.

The real analogue of this routine is F07MEF (SSYTRS/DSYTRS).

9 Example

To solve the system of equations AX = B, where

$$A = \begin{pmatrix} -1.36 + 0.00i & 1.58 + 0.90i & 2.21 - 0.21i & 3.91 + 1.50i \\ 1.58 - 0.90i & -8.87 + 0.00i & -1.84 - 0.03i & -1.78 + 1.18i \\ 2.21 + 0.21i & -1.84 + 0.03i & -4.63 + 0.00i & 0.11 + 0.11i \\ 3.91 - 1.50i & -1.78 - 1.18i & 0.11 - 0.11i & -1.84 + 0.00i \end{pmatrix}$$

and

$$B = \begin{pmatrix} 7.79 + 5.48i & -35.39 + 18.01i \\ -0.77 - 16.05i & 4.23 - 70.02i \\ -9.58 + 3.88i & -24.79 - 8.40i \\ 2.98 - 10.18i & 28.68 - 39.89i \end{pmatrix}.$$

Here A is Hermitian indefinite and must first be factorized by F07MRF (CHETRF/ZHETRF).

9.1 Program Text

Note. The listing of the example program presented below uses bold italicised terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
